

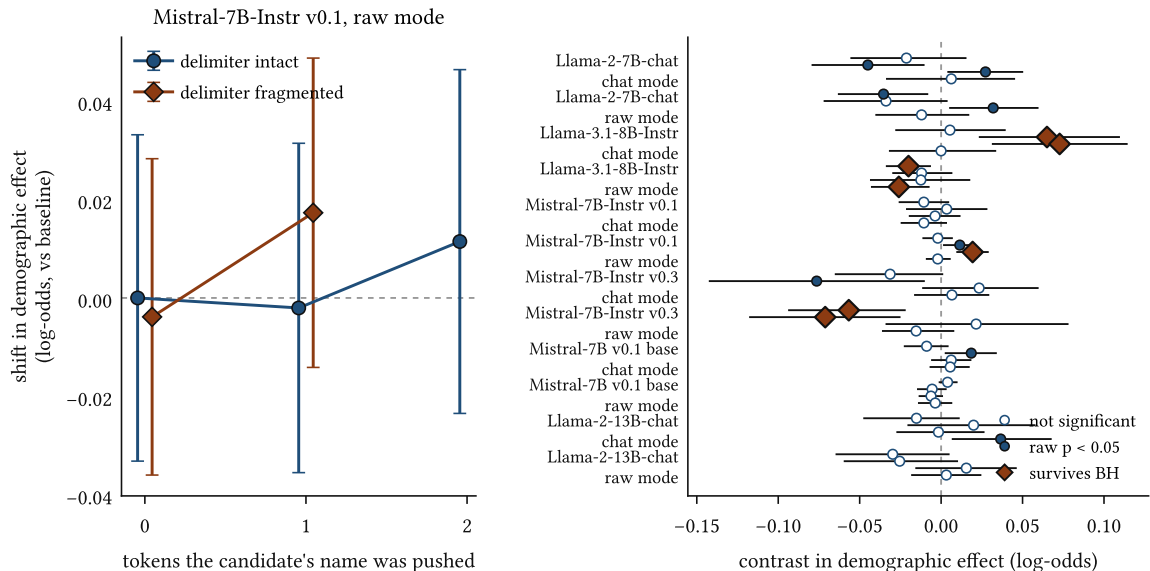

Figure 7. The apparent mechanism was confounded with token position, and little survives once that is controlled. Left: the design that separates the two accounts, on one of the 2 model-modes where fragmentation with position held equal survives correction (3 survive on either fragmentation contrast). The horizontal axis is how far the candidate's name was pushed by the edit; the series are whether a structural delimiter was fragmented. Under a pure position account the two series would coincide. Right: four contrasts per model and inference mode, in each case a paired difference over 72 cells — 24 name pairs crossed with three résumé templates, resampled by pair. Position alone is the control the original eight-condition design lacked; it is not null. Of 48 contrasts drawn here, within a Benjamini-Hochberg family of 168, 7 survive — 4 of the 24 position-only contrasts and 3 of the 24 fragmentation contrasts. The two classes do not separate, which is the finding: moving the name does what fragmenting a delimiter does.
