Mistral v0.1

Mistral v0.3

Figure 1. The unreported choices measured here, each as a multiple of the effect it perturbs. Each bar is the dispersion a single unreported choice contributes to the demographic effect, divided by that model's own effect, on the log-odds scale so the components are commensurable. These are the choices that act on the MEASUREMENT; three further choices act after the data exists -- the resampling unit, the reporting scale and the pairing -- and are not commensurable with these, so they are reported in Sections 6.1 to 6.3 instead. The dashed line at 1.0 is where a choice moves the estimate by as much as the whole effect the study exists to report. The open bar is the measurement noise floor -- what a byte-identical repeat gives -- so every bar taller than it is dispersion rather than error. Solid bars are standard deviations over a set of defensible choices; hatched bars are single shifts between two specific choices, not spreads. On Mistral v0.1 and Mistral v0.3 the denominator is an effect not distinguishable from zero, so those panels' heights say more about a small divisor than about a large numerator. The pairing of Section 6.3 has no bar because re-pairing leaves the mean paired difference algebraically unchanged; it moves the pairwise statistic instead.
