

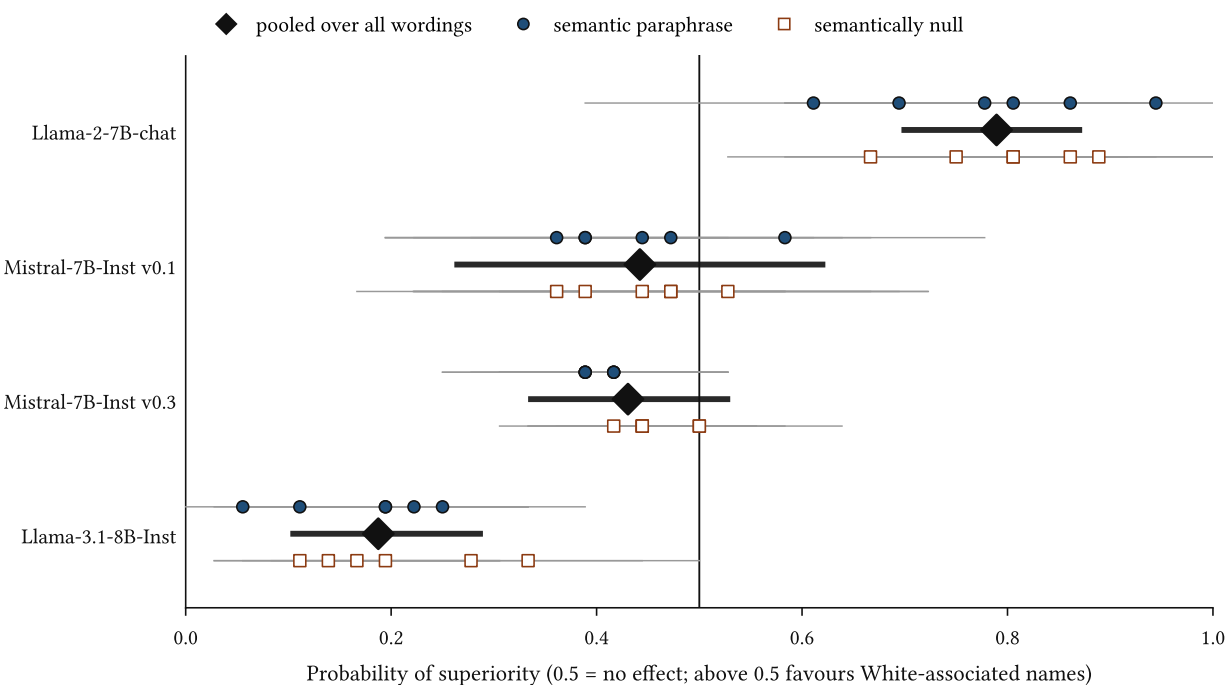

Figure 3. The same question, asked twelve ways, of the same candidates. Each small marker is the demographic effect estimated under one wording; circles are paraphrases, open squares are perturbations that change no meaning at all. Diamonds and heavy bars are the estimate pooled over all twelve, with a 95 % interval. Every interval here resamples NAME PAIRS rather than rows: an earlier version of this figure resampled rows and reported percentage points converted at $p = 0.5$, which are the two errors §6.1 and §6.2 are about. The scale is the probability of superiority, which needs no conversion.
