

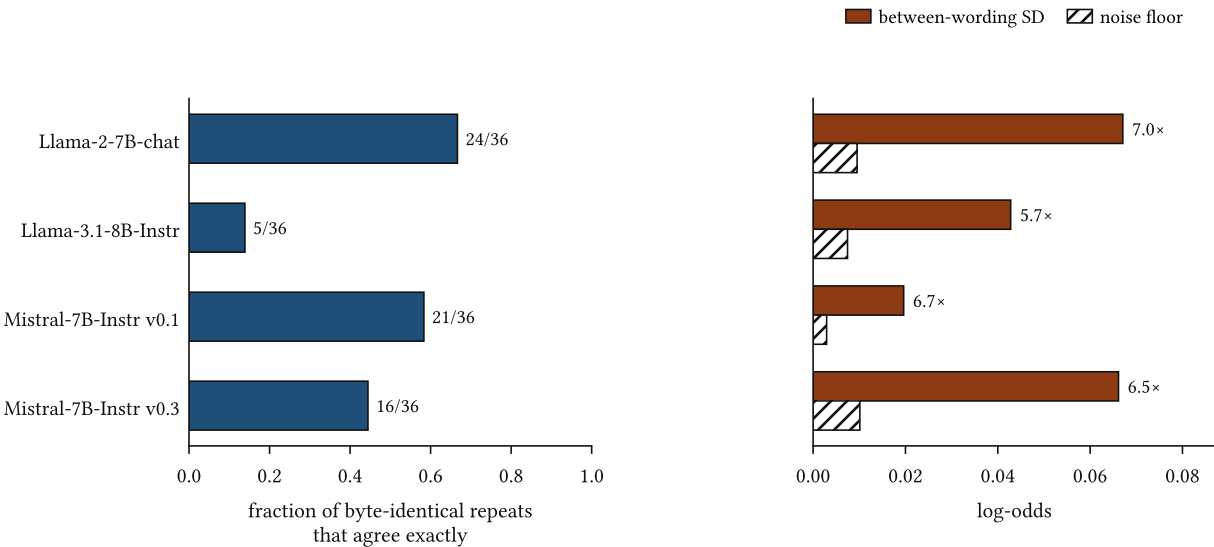

Figure 4. The measurement is not deterministic, and the wording result survives that. Left: two of the twelve wordings are byte-identical by construction, so at temperature 0 they should agree exactly on every cell. They do not. Batching is most of the cause and not all of it: agreement runs 47.9% under concurrent requests and 93.8% once they are forced sequential, and reaches 100% only when key-value cache reuse is disabled as well (§5.2). Re-measuring 504 of these cells on Llama-2-7B-chat in a separate process on a different day reproduced 0 of them exactly. Right: the between-wording standard deviation against the noise expected on a per-wording mean of the same size, estimated from that same replicate. Wording moves the measured effect by five to seven times what the arithmetic does.
